Reversion Alpha DCA Pro

Complete User Guide

Simulate, Optimize, and Execute Quantitative DCA Strategies

Version March 2026 · Not financial advice · For educational and simulation purposes only

Introduction — What Is Reversion Alpha DCA Pro?

Reversion Alpha DCA Pro is a quantitative investment simulation and portfolio tracking platform built by North Prosperity. It is designed to help investors move beyond guesswork and emotion when making regular investment decisions, replacing gut feel with a systematic, data-driven approach to buying and holding assets.

The core idea is simple: not all buying opportunities are equal. An asset trading well below its long-term trend is a far better buying opportunity than the same asset near an all-time high. Reversion Alpha measures exactly this relationship — called the Risk Score — and uses it to tell you not just when to buy, but how much to buy.

The platform supports any publicly traded asset. Simply enter the ticker symbol and the platform loads live historical price data automatically. If it trades and has a price history, Reversion Alpha can simulate it.

Who Is This For?

This platform is designed for long-term investors who make regular contributions to their portfolios — monthly, weekly, or quarterly — and want a disciplined, rules-based framework for deciding how much to invest at any given time. It is not a trading tool. It is an accumulation and distribution strategy simulator.

1. Getting Started — The Header Area

When you open Reversion Alpha DCA Pro, the first thing you see is the application header. This is your command centre. Reading left to right, top to bottom:

1.1 The Title Bar

In the top-right corner you will find two controls you will use regularly:

- **Defaults button** Defaults button — a dropdown that lets you save your current settings as your personal defaults, load them back, or reset to factory settings. Think of this as your personal preset memory. Always save your defaults after configuring the platform to your preferences.
- **Day / Night toggle** Day / Night toggle — switches between dark mode (default) and light mode. Use whichever is most comfortable for your screen environment.

1.2 The Asset & Price Bar

Directly below the title, you will see the currently selected asset ticker in blue (e.g. SPY), followed by the full company or fund name, a Yahoo Finance link, and on the far right the current live price with the day's percentage change in green (up) or red (down).

This bar updates every time you change the selected asset or refresh the page. The price shown is always the most recent market close or live intraday price pulled directly from the data source.

2. The Five Tabs — Your Simulation Modes

Beneath the asset bar you will find four tab buttons. These switch between the different simulation modes and tools. Each tab shares the same input controls but runs a different calculation.

Tab 1 — Equal $ DCA

This is the simplest mode and serves as your benchmark. It simulates what happens if you invest a fixed, identical amount at every scheduled purchase date — regardless of what the market is doing. No risk adjustment, no multipliers. Just the same amount every time.

Use this tab to answer the question: how would a completely passive, mechanical DCA approach have performed compared to my smarter risk-adjusted strategy?

Tab 2 — Lump $um

This tab simulates deploying your entire budget in a single purchase on the start date, rather than spreading it over time. The total amount used equals the same total you would have invested through DCA — making it a fair apples-to-apples comparison.

Use this tab to answer the question: would I have been better off just putting everything in on day one rather than spreading it out over time?

Tab 3 — Precision DCA (the flagship tab)

This is the main event. Precision DCA uses the Risk Score model to dynamically adjust how much you invest at each scheduled purchase date. When the asset is cheap relative to its trend, you invest more. When it is expensive, you invest less or nothing at all.

The result is a strategy that automatically concentrates your buying power at the moments of greatest opportunity — the deep dips — while conserving capital when valuations are stretched. All without any emotional decision-making on your part.

This tab is described in full detail throughout the rest of this guide.

Tab 4 — Portfolio Tracker

A completely separate tool within the platform. The Portfolio Tracker lets you log your actual holdings across multiple assets, see their current values and gains, view live risk scores for each position, and model a target allocation you are working towards. Described in full in Section 8.

3. Setting Up Your Simulation — Input Controls

The controls panel sits below the tabs and is where you configure your simulation. Work through them left to right, top to bottom. Here is exactly what each control does and what you should be looking for as an investor.

3.1 Asset Ticker

Type any asset ticker into the text box and press Enter or click Go. The platform will load live historical price data for that asset. Examples include BTC, SPY, NVDA, TSLA, QQQ, or any valid ticker symbol.

- US stocks and ETFs are supported — enter the standard ticker symbol
- Canadian TSX stocks are supported — add .TO to the end of the ticker (e.g. TD.TO, SHOP.TO)
- Canadian tickers ending in .TO will automatically switch the currency display to CAD

Once you load a ticker the chart and all calculations update automatically with live data pulled in real time.

3.2 USD/CAD Amount

This is your base investment amount per period — the amount you would invest on a standard, no-signal purchase. For example, if you normally invest $1,000 per month, enter 1000 here.

In Precision DCA mode, this amount gets multiplied by the buy multiplier based on the risk score. So a $1,000 base amount might become $3,000 or $5,000 on a deep dip day. In Equal DCA mode this amount is always deployed exactly as entered.

3.3 Currency Toggle

Switch between USD and CAD display. If you are investing in Canadian dollars or tracking a .TO stock, switch to CAD. The platform applies a live USD/CAD conversion rate (fallback rate of 1.36 if the live rate is unavailable). All values — prices, portfolio totals, invested amounts — display in your selected currency.

3.4 Repeat Purchase Frequency

How often do you make your regular investment contributions? Choose from:

- **Daily** Daily — a purchase is simulated on every trading day
- **Weekly** Weekly — a purchase is simulated every Monday
- **Monthly** Monthly — a purchase is simulated on your chosen day of the month (most common for regular investors)
- **Quarterly** Quarterly — a purchase is simulated once per quarter in January, April, July, and October

The platform automatically handles weekends and market holidays — if your scheduled day falls on a non-trading day, the purchase fires on the next available trading day.

3.5 Day of Month

Only visible when frequency is Monthly or Quarterly. Sets the specific day of the month your purchase fires — for example the 13th, the 1st (payday), or the 15th. Match this to your actual investment date for the most accurate simulation.

3.6 Starting Date and the 5-Year Lock

The starting date determines how far back your simulation begins. By default the platform automatically locks your start date to exactly 5 years before the end date — this is shown by the blue 5yr lock button next to the date field.

This auto-lock is useful because it ensures you are always comparing a consistent 5-year window. If you want to test a specific date range — for example starting from the 2022 market bottom — click the lock button to unlock it and set your own start date manually.

You cannot set a start date earlier than the first available data point for the selected asset.

3.7 Ending Date

The end date for your simulation. Defaults to today, giving you a simulation up to the current moment with the latest live price data. You can backdate this to test historical scenarios — for example, what would my DCA strategy have returned if I had started in January 2020 and stopped in December 2023?

4. The Risk Model — The Engine Behind Everything

The Risk Score is the single most important concept in Reversion Alpha. Every buy decision, every multiplier, every sell signal, every chart band — all of it flows from this one number. Understanding it properly is the key to using the platform intelligently.

4.1 What Is the Risk Score?

The Risk Score is a number between 0.0 and 1.0 that measures how expensive or cheap an asset currently is relative to its own long-term trend. Think of it as a thermometer for valuation:

Risk Score	Signal	What It Means
0.00 – 0.10	Extreme Buy	Asset is dramatically below its long-term trend. Historically rare. Maximum accumulation zone.
0.10 – 0.20	Strong Buy	Asset is significantly below trend. Deep value territory. Heavy buying signal.
0.20 – 0.30	Buy	Asset is moderately below trend. Good buying opportunity.
0.30 – 0.40	Accumulate	Asset is slightly below trend. Reasonable entry.
0.40 – 0.50	Neutral / Base	Asset near fair value relative to trend. Standard DCA zone.
0.50 – 0.60	Caution	Asset slightly above trend. Reduce new buying.
0.60 – 0.70	Hold	Asset above trend. No new buying unless band is set high.
0.70 – 0.80	Reduce	Asset well above trend. Consider trimming position.
0.80 – 1.00	Extreme Caution	Asset far above trend. Historically associated with market tops.

4.2 The 500-Day Geometric Moving Average (MA500)

The MA500 is the backbone of the risk model. A moving average is simply the average price of an asset over a rolling window of time. The 500-day window means we are always looking at roughly the past 20 months of price history to establish what the trend looks like.

But why geometric rather than the simple arithmetic average most people are familiar with? The geometric mean multiplies all the values and takes the nth root, rather than adding them and dividing. This has two important properties for financial data:

- It handles the asymmetry of price movements correctly — a 50% drop requires a 100% gain to recover, and the geometric mean reflects this properly

- It gives a smoother, more stable trend line that is less distorted by short-term spikes at either extreme

The 500-day window was specifically chosen because it is long enough to stay elevated through sustained bear markets like the 2022 crypto crash. A shorter window — say 200 days — would have dropped rapidly as prices fell in 2022, making the risk scores appear falsely moderate when in reality assets were at historic lows. The 500-day window kept the MA high, which correctly produced very low risk scores (deep buy signals) throughout the entire 2022 bear market.

Real World Example

In November 2022 Bitcoin was trading around $16,000 while its 500-day moving average was approximately $32,000 — meaning Bitcoin was trading at roughly half its trend value. This produced an extreme buy signal. Investors using this system were buying heavily at exactly the right time.

4.3 Risk Score Calibration

The model has been carefully calibrated against known historical market extremes to ensure the risk scores are meaningful and consistent across different assets and time periods:

Date	Asset Price	MA500 (approx)	Risk Score	Verdict
Jun 2022	$22,000	~$41,000	0.155	Deep buy — correct
Jul 2022	$19,000	~$38,000	0.118	Deep buy — correct
Nov 2022	$16,000	~$32,000	0.197	Deep buy — correct
Apr 2023	$30,000	~$22,000	0.532	Above band — no buy
Feb 2026	$69,000	~$95,000	0.324	Moderate buy — correct

5. Precision DCA Controls — Fine-Tuning Your Strategy

When you are on the Precision DCA tab, an additional row of controls appears below the standard settings. These are the levers that define exactly how your risk-adjusted strategy behaves.

5.1 Accumulate Up To Risk... (The Risk Band)

This is the most important setting in Precision DCA mode. It defines your personal buying threshold — the maximum risk score at which you are willing to make a standard 1x purchase.

Think of it as your valuation ceiling. If you set the band to 0.4–0.5, you are saying: I will buy at standard size when the risk score is between 0.4 and 0.5, and I will buy more aggressively at anything below 0.4. I will not buy at all above 0.5.

The eight available bands range from 0.0–0.1 (only buy at extreme dips) all the way to 0.7–0.8 (willing to buy even when the asset is quite elevated). The default of 0.4–0.5 is a balanced starting point suitable for most investors.

Investor Tip

A more conservative investor might choose a lower band like 0.3–0.4, meaning they only start buying when the asset is already meaningfully below trend. A more aggressive investor comfortable with higher valuations might choose 0.5–0.6. There is no universally right answer — it depends on your time horizon and risk tolerance.

5.2 Buying Strategy — Linear vs Exponential

Once you have set your risk band, you need to decide how aggressively the buy amounts scale as the price drops further below your band. There are two modes:

Linear Strategy

The buy multiplier increases by 1 for each 0.1-wide risk tier below your band. If your band is 0.4–0.5, the multipliers work as follows:

Risk Zone	Multiplier	Buy Amount (base $1,000)
0.4 – 0.5 (your band)	1x	$1,000
0.3 – 0.4	2x	$2,000
0.2 – 0.3	3x	$3,000
0.1 – 0.2	4x	$4,000
0.0 – 0.1	5x	$5,000

Exponential Strategy

The buy multiplier doubles for each tier below your band. This creates much larger purchases at extreme dip levels:

Risk Zone	Multiplier	Buy Amount (base $1,000)
0.4 – 0.5 (your band)	1x	$1,000
0.3 – 0.4	2x	$2,000
0.2 – 0.3	4x	$4,000
0.1 – 0.2	8x	$8,000
0.0 – 0.1	16x	$16,000

Linear is more conservative and predictable — your maximum single purchase is 5x your base. Exponential is more aggressive and can deploy very large amounts at extreme dips, but requires sufficient capital reserves to fund the 8x and 16x purchases. Most investors should start with Linear.

5.3 Deep Value — The Lightning Bolt Zone

When enabled, this setting doubles the buy multiplier whenever the risk score drops below 0.10. This is the rarest zone in the entire model — it has historically only occurred a handful of times in any asset's history, representing genuine market panics or crash conditions.

With Deep Value enabled on Linear mode, a risk score below 0.10 triggers a 10x purchase instead of 5x. On Exponential mode it becomes 32x. This feature is for investors who want to maximise their position during black swan buying opportunities.

Important

Deep Value is a powerful feature but requires careful consideration of your available capital. If you cannot fund a 10x or 32x purchase, do not enable this without also having a reserve fund set aside specifically for these rare events.

5.4 Scale — Lin vs Log

This toggles the Y-axis of the portfolio value chart between a linear scale and a logarithmic scale. For assets that have grown dramatically over the simulation period (e.g. Bitcoin going from $7,000 to $100,000), a linear scale compresses all the early price action into a flat line. Switching to Log scale makes the percentage growth at every stage of the asset's history visible and comparable.

5.5 Risk Offset — Auto-Vol and Manual

The Risk Offset is a fine-tuning mechanism that shifts the risk score up or down by a fixed amount before it is compared against your band. This allows you to calibrate the strategy for the current volatility environment of the asset.

Auto-Vol (recommended)

When the Auto-Vol toggle is active (shown in blue), the platform automatically calculates the appropriate offset based on the asset's current volatility relative to its own historical range. Specifically:

- The platform computes the rolling 60-day annualised volatility for every period in the asset's history
- It then ranks the current 60-day volatility as a percentile within that history — so a score of 0% means the asset is currently at its calmest ever, and 100% means it is at its most volatile ever
- Low volatility percentile (calm market) → more negative offset (e.g. −0.10) → more aggressive buying
- High volatility percentile (turbulent market) → less negative offset (e.g. −0.01) → more cautious buying

This means the strategy automatically becomes more aggressive when markets are unusually calm and more conservative when markets are unusually turbulent — which is exactly the right behaviour.

Manual Offset

Click the toggle to switch to Manual mode. A slider appears allowing you to set the offset anywhere from −0.20 to +0.20. A negative offset effectively lowers all risk readings, making the strategy more aggressive. A positive offset raises them, making it more conservative. The current effective offset value is always shown in blue next to the label.

6. Reading the Charts

6.1 The Portfolio Value Chart (top chart)

This chart shows the growth of your simulated portfolio over the selected date range. Three lines are plotted:

- **Blue area** Blue shaded area — your DCA portfolio value. This is the market value of all shares accumulated through your strategy at every point in time.
- **Grey dashed** Grey dashed line — your total invested cost basis. This is the running total of all cash you have deployed. When the blue area is above this line, your strategy is profitable.
- **Dark dotted** Dark dotted line — the lump sum equivalent. This shows what would have happened if you had invested the same total amount all at once on the start date. Comparing this against the DCA line shows you whether spreading your purchases over time outperformed a single large entry.

The Y-axis shows portfolio value in your selected currency. The X-axis shows dates across the simulation period.

6.2 The Risk Strategy Chart (bottom chart)

This is the most information-dense chart on the platform. It overlays three things simultaneously:

- **Blue line** Blue/white line — the risk score, plotted against the left Y-axis (0.0 to 1.0). Watch this line to understand the historical rhythm of the asset's valuation cycles.
- **Red dotted** Red dotted line — the asset price, plotted against the right Y-axis (in your currency). This lets you see exactly how price movements correspond to risk score movements.
- **Coloured bands** Coloured bands — the buy zones. Each horizontal band represents a risk tier and is labelled with the buy amount and multiplier that would trigger there (e.g. Buy $3,000 (3x)). Darker green means a deeper dip and a higher multiplier. The yellow band at the bottom is the Deep Value zone.

The current risk score is displayed in the top-right corner of this chart header in a colour-coded number — yellow for deep value, green for buy zones, blue for neutral, orange for elevated, red for extreme.

6.3 Reading the Charts Together

The most powerful way to use these charts is to watch them together. When the blue risk line dips into the green bands in the bottom chart, you will see corresponding purchases firing in the trade log below, and the portfolio value line in the top chart will often show an inflection point — the buying at low prices that later drives the portfolio higher.

7. Advanced Features

7.1 Sell Strategy

By default the platform is accumulation-only — it never sells. Enabling the Sell Strategy adds automatic trim signals at market tops. When the risk score climbs into extreme territory, the strategy sells a small percentage of your position to lock in profits.

- Sell 5% of your position when risk reaches 0.90 to 0.949 — the asset is significantly overvalued
- Sell 10% of your position when risk reaches 0.95 or above — the asset is in extreme overvaluation territory

Each sell event appears in the trade log with the proceeds recorded. The statistics panel shows total sell proceeds, number of sell events, and the net P&L including vs. a portfolio that never sold. This helps you quantify whether the trim-at-peak strategy added or reduced returns in any given scenario.

7.2 LEAP Options

LEAP (Long-term Equity Anticipation) options are long-dated call options — contracts that give you the right to buy shares at a fixed price for up to 18 months. When enabled, the platform replaces direct share purchases in the deepest risk zone (0.00 – 0.099) with simulated LEAP contracts.

Why would you do this? Because at the deepest dips — when an asset is trading at extreme discounts to its trend — LEAPs provide leveraged upside if the price recovers. Instead of buying $5,000 worth of shares, you might buy $5,000 worth of LEAP contracts that control a much larger notional position.

How the simulation works:

- Strike price is set at 92% of the entry price — slightly in the money
- Each contract controls 100 shares, costing a percentage of the share price (default 40%, adjustable)
- Any remaining budget after buying whole contracts is used to purchase shares directly
- After 18 months, the contract expires and the intrinsic value (if any) is calculated: max(0, price − strike) × shares
- Extrinsic (time) value decays linearly over the 18-month term

The approximate leverage multiplier is shown on screen — at 40% cost, a LEAP provides approximately 2.5x leverage on the upside.

> **Important Note**
> LEAP options involve real risk. If the asset does not recover above the strike price before expiry, the option expires worthless and the entire premium paid is lost. The simulation models this accurately — expired worthless positions are shown as losses in the trade log.

7.3 Covered Calls

Covered calls are an income-generating strategy for investors who already hold a significant position. When enabled, the platform simulates selling call options against your existing holdings when the risk score rises above 0.90 — meaning the asset is significantly overvalued and likely to be range-bound or declining.

By selling a covered call you collect a premium upfront in exchange for agreeing to potentially sell your shares at a fixed price. The premium provides income even if the share price stagnates or falls slightly. The trade-off is that you cap your upside on half your position.

The monthly premium percentage is adjustable (default 0.40% of position value per month). The simulation shows total covered call income in the statistics panel and logs each event in the trade log.

7.4 Initial Position

If you already own shares of an asset before the simulation start date, you can inject that existing position into the simulation. This allows the platform to calculate your true portfolio performance including all prior holdings, not just new purchases made during the simulation window.

Enter the purchase date, number of shares or units, and the average price you paid. The platform will include this position in all portfolio value calculations, gain/loss figures, and average cost computations from that date forward.

If your initial purchase date is before the simulation start date, the position is injected at the beginning of the simulation automatically.

7.5 Defaults — Saving Your Settings

Once you have configured the platform to your personal preferences — your asset, base amount, risk band, strategy, frequency, and advanced features — you can save everything as your personal defaults using the Defaults dropdown in the top-right corner.

These defaults persist across sessions. Every time you open the platform, your saved settings load automatically. You can update defaults at any time, or reset to the factory settings if you want to start fresh.

8. The Portfolio Tracker Tab

The Portfolio Tracker is a standalone tool within the platform for managing and monitoring your real-world portfolio across multiple assets simultaneously. It has two sub-sections: Actual Holdings and Planned Allocation.

8.1 Actual Holdings

This is where you log everything you currently own. For each holding, enter:

- Ticker — the asset symbol (e.g. NVDA, BTC, SPY)
- Shares / Units — how many units you hold
- Entry Price — your average cost basis per unit

Once entered, the platform fetches the current live price for each ticker and calculates:

- Current Value — shares × current price
- Gain / Loss — current value minus total cost, in both dollars and percentage
- Current Risk Score — the real-time risk reading for that asset, colour coded so you can instantly see which holdings are in buy, hold, or reduce territory
- Action Badge — a colour-coded recommendation label: Strong Buy, Buy, Hold, Reduce, or Sell

You can also toggle on the CAGR row for each holding. This shows the asset's historical Compound Annual Growth Rate over 1, 3, 5, and 10 year periods, plus forward-looking estimates at 5, 10, 20, and 30 year horizons based on a mean-reversion model. These forward estimates are colour coded — green for strong expected returns, amber for moderate, red for poor.

A summary footer shows your total portfolio value, total cost, total gain/loss, and number of holdings.

Data Persistence

Your portfolio holdings are automatically saved to your browser's local storage every time you make a change. They will still be there the next time you open the platform on the same device and browser. Note that clearing your browser data will erase your saved portfolio.

8.2 Planned / Target Allocation

The Planned tab lets you model a target portfolio — what you want your holdings to look like in the future. Enter your target tickers, the number of shares you intend to hold, and your planned entry price. The platform fetches live prices and shows you:

- What your planned portfolio would be worth at current prices
- The difference between your planned portfolio value and your actual portfolio value
- The projected gain or loss on each planned position
- The current risk score for each target — helping you decide if now is a good time to start building a position

This is particularly useful for building a watchlist of assets you want to accumulate and tracking how their risk scores evolve over time, so you can begin buying when the signal is right.

9. The Statistics Panel

To the right of the charts sits the statistics panel — a live summary of everything the simulation has calculated. Here is what each metric means:

Metric	What It Means
Total Invested	The total amount of cash deployed across all purchases in the simulation. This is your cost basis — what you actually spent.
Accumulated Asset	The total number of shares or units accumulated through all purchases. Also shows your average cost per unit and the current last price.
Portfolio Value	The current market value of your accumulated holdings at the latest price. This is what your position is worth right now.
Gain / Loss	The difference between Portfolio Value and Total Invested, shown in both dollars and percentage. Green means you are ahead, red means you are behind.
DCA CAGR	The Compound Annual Growth Rate of your DCA strategy — what percentage per year your money has grown at, annualised.
Lump Sum Value	What the same total invested amount would be worth today if deployed as a single purchase on the start date.
Lump CAGR	The annualised return of the lump sum strategy for comparison.
Buy Count	How many scheduled purchase events fired during the simulation — i.e. how many times the risk score was within your band.
Sell Count	How many sell events fired (only shown if Sell Strategy is enabled).
Sell Proceeds	Total cash received from all sell events.
LEAP Count	Number of LEAP option purchases made (only if LEAP is enabled).
LEAP Value	Current mark-to-market value of open LEAP positions plus any realised P&L from expired contracts.
CC Income	Total covered call premium income collected (only if Covered Calls is enabled).
Daily Change	The asset's price change since the previous day, shown as a percentage.

10. The Trade Log

Below the statistics panel is the full trade log — a chronological record of every event that occurred during the simulation. Each row represents one purchase, sell, LEAP, covered call, or initial position injection.

Column	What It Shows
Date	The date the event occurred.
Action	What happened — Buy 1x, Buy 3x, Sell 10%, LEAP 0.75Δ, Covered Call, Initial Position, or None.
Risk	The risk score at the time of the event. This tells you exactly what the valuation was when each buy or sell was triggered.
Price	The asset price on that date.
Amount	The dollar amount invested or the LEAP premium paid.
Proceeds	For sell events, the cash received from selling shares.
CC Income	For covered call events, the premium income collected.
Accumulated	The running total of shares held after this event.
Invested	The running total of cash deployed after this event.
Value	The portfolio market value at this point in time.

The trade log is extremely useful for understanding exactly how the strategy performed — you can see which purchases were made at the lowest risk scores, how the position built over time, and where sell events trimmed the portfolio at peaks.

11. Step-by-Step Setup Guide for New Users

Follow these steps in order when setting up the platform for the first time:

1. Open the platform and ensure you are on the Precision DCA tab.
2. In the Asset Ticker box, type the ticker of the asset you want to simulate and press Enter or click Go. Wait for the data to load — you will see a green Live data confirmation appear.
3. Set your USD/CAD Amount to your typical monthly investment amount — the amount you can comfortably invest on a standard purchase.
4. Select your Currency — USD for US-listed assets, CAD if you are investing in Canadian dollars.
5. Set your Repeat Purchase Frequency to match how often you invest. Monthly is most common.
6. If Monthly or Quarterly, set your Day of Month to match your actual investment date (e.g. the day after your payday).
7. Leave the Starting Date on auto-lock (5yr) for your first simulation. You can always change it later.
8. Set the Ending Date to today to simulate up to the current moment.
9. Choose your Risk Band. Start with the default 0.4–0.5 if you are unsure. You can experiment with other bands once you understand how the strategy works.
10. Choose Linear strategy if you are new to the platform. Exponential is more powerful but requires larger capital reserves for deep dip events.
11. Leave Deep Value Off for your first simulation.
12. Leave Risk Offset on Auto-Vol. The platform will automatically calibrate for the current volatility environment.
13. Leave Sell Strategy Off for your first simulation. Focus on accumulation first.
14. Leave LEAP and Covered Call Off for your first simulation — these are advanced features.
15. If you have an existing position in this asset, enable Initial Position and enter your purchase date, shares, and average price paid.
16. Review the charts and statistics. Look at how many times the risk score entered your buy zone, what multipliers were triggered, and how the DCA portfolio value compares to the lump sum and total invested lines.
17. When you are happy with your settings, click Defaults and save them as your personal defaults so they load automatically next time.

Pro Tip

Run the simulation on the same asset with different risk bands side by side (by changing the band and noting the results) to find the band that would have produced the best outcome historically. Then ask yourself whether that band matches your real-world cash flow capacity — if the 0.2–0.3 band would have been best but you cannot fund 5x purchases, a higher band that you can actually execute is always better than a theoretically optimal band you cannot afford to follow.
